SPI Real time clock/calendar Rev. 02 — 4 December 2009

Product data sheet

General description

The PCF2123 is a CMOS¹ Real-Time Clock (RTC) and calendar optimized for low power applications. Data is transferred serially via a Serial Peripheral Interface (SPI-bus) with a maximum data rate of 6.25 Mbit/s. An alarm and timer function is also available providing the possibility to generate a wake-up signal on an interrupt pin. An offset register allows fine tuning of the clock.

Features 2.

- Real time clock provides year, month, day, weekday, hours, minutes, and seconds based on a 32.768 kHz quartz crystal
- Low backup current while running: typical 100 nA at V_{DD} = 2.0 V and T_{amb} = 25 °C
- Resolution: seconds to years
- Watchdog functionality
- Freely programmable timer and alarm with interrupt capability
- Clock operating voltage: 1.1 V to 5.5 V
- 3 line SPI-bus with separate, but combinable data input and output
- Serial interface at V_{DD} = 1.6 V to 5.5 V
- 1 second or 1 minute interrupt output
- Integrated oscillator load capacitors for C_L = 7 pF
- Internal Power-On Reset (POR)
- Open-drain interrupt and clock output pins
- Programmable offset register for frequency adjustment

Applications

- Time keeping application
- Battery powered devices
- Metering
- High duration timers
- Daily alarms
- Low standby power applications

The definition of the abbreviations and acronyms used in this data sheet can be found in Section 19.

SPI Real time clock/calendar

7. Pinning information

7.1 Pinning

SPI Real time clock/calendar

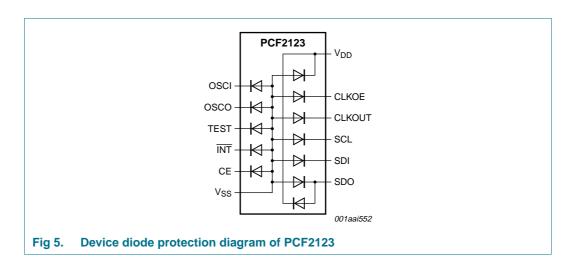

7.2 Pin description

Table 3. Pin description

Symbol	Pin			Description			
	TSSOP14	HVQFN16	PCF2123Ux				
OSCI	1	16	7	oscillator input; high-impedance node; minimize wire length between quartz and package			
osco	2	1	8	oscillator output; high-impedance node; minimize wire length between quartz and package			
n.c.	3, 11	6, 7, 14, 15	-	do not connect and do not use as feed through; connect to $V_{\mbox{\scriptsize DD}}$ if floating pins are not allowed			
TEST	4	2	9	test pin; not user accessible; connect to V_{SS} or leave floating (internally pulled down)			
ĪNT	5	3	10	interrupt output (open-drain; active LOW)			
CE	6	4	11	chip enable input (active HIGH) with internal pull down			
V_{SS}	7	5 <mark>[1]</mark>	12 <mark>2</mark>	ground			
SDO	8	8	1	serial data output, push-pull; high-impedance when not driving; can be connected to SDI for single wire data line			
SDI	9	9	2	serial data input; may float when CE is inactive			
SCL	10	10	3	serial clock input; may float when CE is inactive			
CLKOE	12	11	4	CLKOUT enable or disable pin; enable is active HIGH			
CLKOUT	13	12	5	clock output (open-drain)			
V_{DD}	14	13	6	supply voltage; positive or negative steps in V_{DD} may affect oscillator performance; recommend 100 nF decoupling close to device (see Figure 29)			

^[1] The die paddle (exposed pad) is wired to V_{SS} but should not be electrically contacted.

8. Device protection diagram

^[2] The substrate (rear side of the die) is wired to V_{SS} but should not be electrically contacted.

SPI Real time clock/calendar

9. Functional description

The PCF2123 contains 16 8-bit registers with an auto-incrementing address counter, an on-chip 32.768 kHz oscillator with two integrated load capacitors, a frequency divider which provides the source clock for the Real Time Clock (RTC), a programmable clock output, and a 6.25 Mbit/s SPI-bus. An offset register allows fine tuning of the clock.

All 16 registers are designed as addressable 8-bit parallel registers although not all bits are implemented.

- The first two registers (memory address 00h and 01h) are used as control registers.
- The memory addresses 02h through 08h are used as counters for the clock function (seconds up to years). The registers Seconds, Minutes, Hours, Days, Weekdays, Months, and Years are all coded in Binary Coded Decimal (BCD) format. When one of the RTC registers is read the contents of all counters are frozen. Therefore, faulty reading of the clock and calendar during a carry condition is prevented.
- Addresses 09h through 0Ch define the alarm condition.
- Address 0Dh defines the offset calibration.
- Address 0Eh defines the clock out and timer mode.
- Address registers 0Eh and 0Fh are used for the countdown timer function. The
 countdown timer has four selectable source clocks allowing for countdown periods in
 the range from 244 μs up to four hours. There are also two pre-defined timers which
 can be used to generate an interrupt once per second or once per minute. These are
 defined in register Control_2 (01h).

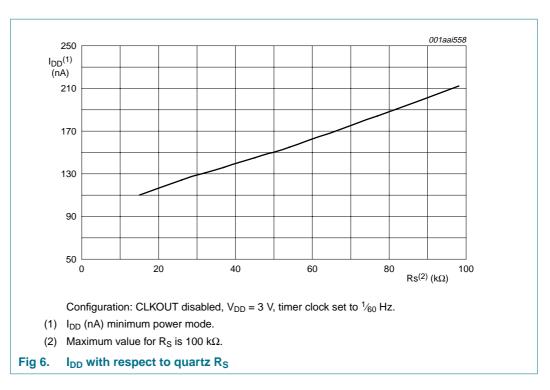

9.1 Low power operation

Minimum power operation will be achieved by reducing the number and frequency of switching signals inside the IC, i.e., low frequency timer clocks and a low frequency CLKOUT will result in lower operating power. A second prime consideration is the series resistance $R_{\rm s}$ of the quartz used.

9.1.1 Power consumption with respect to quartz series resistance

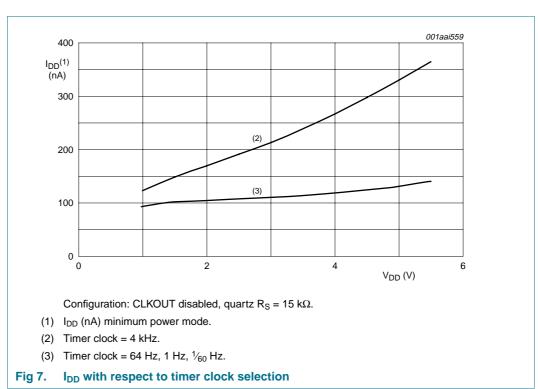

The series resistance acts as a loss element. Low R_{s} will reduce current consumption further.

SPI Real time clock/calendar

9.1.2 Power consumptions with respect to timer mode

Four source clocks are possible for the timer. The 4.096 kHz source clock will add the greatest part to the power consumption. The selection of 64 Hz, 1 Hz or $^{1}/_{60}$ Hz will be almost indistinguishable and add very little.

SPI Real time clock/calendar

9.2 Register overview

16 registers are available. The time registers are encoded in the Binary Coded Decimal (BCD) format to simplify application use. Other registers are either bit-wise or standard binary.

Table 4. Registers overview

Bit positions labelled as - are not implemented and will return a 0 when read. Bit positions labelled with N should always be written with logic 0^[1].

Address	Register name	Bit								
		7	6	5	4	3	2	1	0	
Control a	nd status registers					'			•

9.3 Control registers

9.3.1 Register Control_1

Table 5. Control_1 - control and status register 1 (address 00h) bit description

Bit	Symbol	Value	Description	Reference
7	EXT_TEST	0[1]	normal mode	Section 9.12
		1	external clock test mode	
6	N	-	unused	-
5	STOP	0[1]	the RTC source clock runs	Section 9.13
		1	the RTC clock is stopped;	
			RTC divider chain flip-flops are asynchronously set to logic 0;	
			CLKOUT at 32.768 kHz, 16.384 kHz or 8.192 kHz is still available	
4	SR	0[1]	no software reset	Section 9.5
		1	initiate software reset[2];	
			this register will always return a 0 when read	
3	N	-	unused	-
2	12_24	0[1]	24 hour mode is selected	-
		1	12 hour mode is selected	
1	CIE	0[1]	no correction interrupt generated	Section 9.11
		1	interrupt pulses will be generated at every correction cycle	
0	N	-	unused	-

^[1] Default value.

^[2] For a software reset, 01011000 (58h) must be sent to register Control_1 (see Section 9.5).

SPI Real time clock/calendar

9.3.2 Register Control_2

Table 6. Control 2 - control and status register 2 (address 01h) bits description

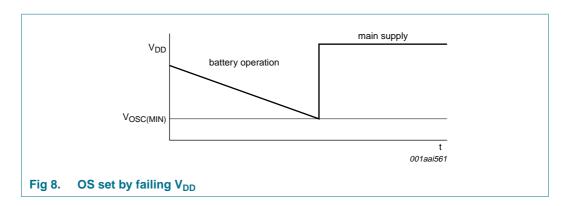

Bit	Symbol	Value	Description	Reference
7	MI	0 <u>[1]</u>	minute interrupt is disabled	Section 9.8.3
		1	minute interrupt is enabled	
6	SI	0[1]	second interrupt is disabled	
		1	second interrupt is enabled	
5	MSF	0[1]	no minute or second interrupt generated	
		1	flag set when minute or second interrupt generated;	
			flag must be cleared to clear interrupt when $TI_IP = 0$	
4	TI_TP	0[1]	interrupt pin follows timer flags	Section 9.9.2
		1	interrupt pin generates a pulse	
3	AF	0[1]	no alarm interrupt generated	Section 9.7.5
		1	flag set when alarm triggered;	
			flag must be cleared to clear interrupt	
2	TF	0[1]	no countdown timer interrupt generated	Section 9.8.4
		1	flag set when countdown timer interrupt generated;	
			flag must be cleared to clear interrupt when $TI_IP = 0$	
1	AIE	0[1]	no interrupt generated from the alarm flag	Section 9.9.3
		1	interrupt generated when alarm flag set	
0	TIE	0[1]	no interrupt generated from the countdown timer	Section 9.9.2
		1	interrupt generated by the countdown timer	

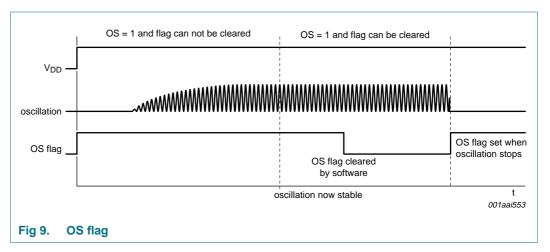

^[1] Default value.

9.4 OS flag

The PCF2123 includes a flag (OS in register Seconds, see <u>Table 8</u>) which is set whenever the oscillator is stopped (see <u>Figure 8</u> and <u>Figure 9</u>). The flag will remain set until cleared by software. If the flag cannot be cleared, then the PCF2123 oscillator is not running. This method can be used to monitor the oscillator and to determine if the supply voltage has reduced to the point where oscillation fails.

SPI Real time clock/calendar

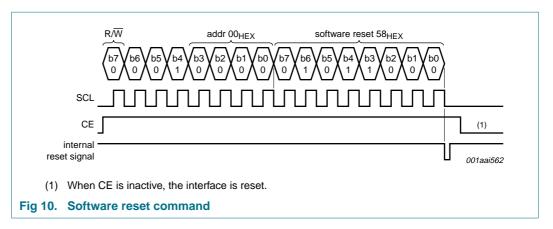

The oscillator may be stopped, for example, by grounding one of the oscillator pins, OSCI or OSCO. The oscillator is also considered to be stopped during the time between power-on and stable crystal resonance. This time may be in the range of 200 ms to 2 s depending on crystal type, temperature and supply voltage. At power-on the OS flag is always set.

9.5 Reset

A reset is automatically generated at power-on. A reset can also be initiated with the software reset command. It is generally recommended to make a software reset after power-on.

A software reset can be initiated by setting the bits 6, 4 and 3 in register Control_1 logic 1 and all other bits logic 0 by sending the bit sequence 01011000 (58h), see <u>Figure 10</u>. If this bit sequence is not correct, the software reset instruction will be ignored to protect the device from accidently being reset. When sending the software instruction, the other bits are not written.

SPI Real time clock/calendar

After reset, the following mode is entered:

- 32.768 kHz on pin CLKOUT active
- 24 hour mode is selected
- Offset register is set to 0
- No alarms set
- Timer disabled
- No interrupts enabled

Table 7. Register reset values

Bits labeled as - are not implemented. Bits labeled as X are undefined at power-on and unchanged by subsequent resets.

Address	Register name	Bit							
		7	6	5	4	3	2	1	0
00h	Control_1	0	0	0	0	0	0	0	0
01h	Control_2	0	0	0	0	0	0	0	0
02h	Seconds	1	Χ	Χ	Χ	Χ	Χ	Χ	Х
03h	Minutes	-	Χ	Χ	Χ	Χ	Χ	Χ	Х
04h	Hours	-	-	Χ	Χ	Χ	Χ	Χ	Χ

Bit	Symbol	Value	Place value	Description
7 to 4	YEARS	0 to 9	ten's place	actual year coded in BCD format
3 to 0		0 to 9	unit place	

9.6.8 Setting and reading the time

Figure 11 shows the data flow and data dependencies starting from the 1 Hz clock tick.

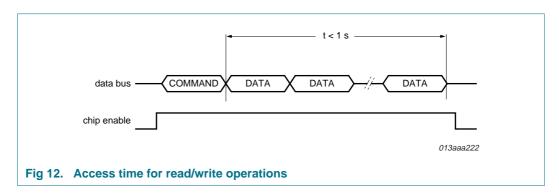

SPI Real time clock/calendar

During read/write operations, the time counting circuits (memory locations 02h through 08h) are blocked.

This prevents

- Faulty reading of the clock and calendar during a carry condition
- Incrementing the time registers during the read cycle

After this read/write access is completed, the time circuit is released again and any pending request to increment the time counters that occurred during the read/write access is serviced. A maximum of 1 request can be stored; therefore, all accesses must be completed within 1 second (see Figure 12).

As a consequence of this method, it is very important to make a read or write access in one go, that is, setting or reading seconds through to years should be made in one single access. Failing to comply with this method could result in the time becoming corrupted.

As an example, if the time (seconds through to hours) is set in one access and then in a second access the date is set, it is possible that the time may increment between the two accesses. A similar problem exists when reading. A roll over may occur between reads thus giving the minutes from one moment and the hours from the next. Therefore it is advised to read all time and date registers in one access.

9.7 Alarm function

When one or more of these registers are loaded with a valid minute, hour, day, or weekday and its corresponding alarm enable bit (AE_x) is logic 0, then that information will be compared with the current minute, hour, day, and weekday.

9.7.1 Register Minute_alarm

Table 18. Minute_alarm - minute alarm register (address 09h) bit description

Bit	Symbol	Value	Place value	Description		
7	AE_M 0 -		-	minute alarm is enabled		
		1[1]	-	minute alarm is disabled

3 to 0	-	0 to 9	unit place	format		

^[1] Default value.

SPI Real time clock/calendar

9.7.2 Register Hour_alarm

Table 19. Hour_alarm - hour alarm register (address 0Ah) bit description

Bit	Symbol	Value	Place value	Description
7	AE_H	0		hour alarm is enabled
		1[1]		hour alarm is disabled
6	-	-		unused
12 h	our mode[2]			
5	AMPM	0		indicates AM
		1		indicates PM
4	HOUR_ALARM	0 to 1	ten's place	hour alarm information coded in BCD
3 to 0)	0 to 9	unit place	format when in 12 hour mode
24 h	our mode[2]			
5 to 4 HOUR_ALARM		0 to 2 ten's place		hour alarm information coded in BCD
3 to 0)	0 to 9	unit place	format when in 24 hour mode

^[1] Default value.

9.7.3 Register Day_alarm

Table 20. Day_alarm - day alarm register (address 0Bh) bit description

Bit	Symbol	Value	Place value	Description	
7	AE_D	0	-	day alarm is enabled	
		1[1]	-	day alarm is disabled	
6	-	-	-	unused	
5 to 4	DAY_ALARM	0 to 3	ten's place	day alarm information coded in BCD	
3 to 0		0 to 9	unit place	format	

^[1] Default value.

9.7.4 Register Weekday_alarm

Table 21. Weekday_alarm - weekday alarm register (address 0Ch) bit description

Bit	Symbol	Value	Description
7	AE_W	0	weekday alarm is enabled
		1[1]	weekday alarm is disabled
6 to 3	-	-	unused
2 to 0	WEEKDAY_ALARM	0 to 6	weekday alarm information coded in BCD format

^[1] Default value.

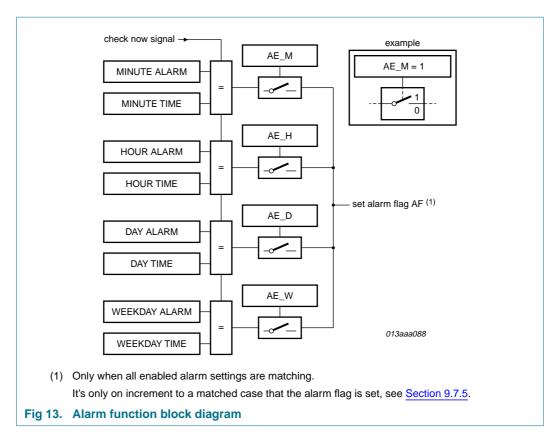

9.7.5 Alarm flag

By clearing the MSB, AE_x (Alarm Enable), of one or more of the alarm registers the corresponding alarm condition(s) are active. When an alarm occurs, AF (register Control_2, see <u>Table 6</u>) is set logic 1. The asserted AF can be used to generate an interrupt (<u>INT</u>). The AF is cleared using the interface.

© NXP B.V. 2009. All rights reserved.

^[2] Hour mode is set by the 12_24 bit in register Control_1.

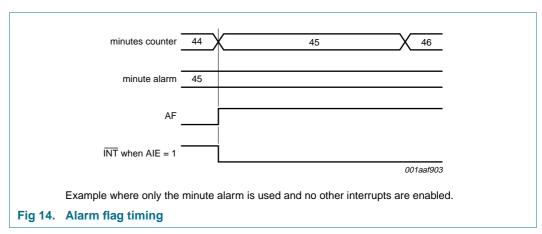

SPI Real time clock/calendar

The registers at addresses 09h through 0Ch contain alarm information. When one or more of these registers is loaded with minute, hour, day, or weekday, and its corresponding Alarm Enable bit (AE_x) is logic 0, then that information is compared with the current minute, hour, day, and weekday. When all enabled comparisons first match, the Alarm Flag (AF) is set logic 1.

The generation of interrupts from the alarm function is controlled via bit AIE (register Control_2, see Table 6). If bit AIE is enabled, the INT pin follows the condition of bit AF. AF will remain set until cleared by the interface. Once AF has been cleared, it will only be set again when the time increments to match the alarm condition once more. Alarm registers which have their AE_x bit logic 1 are ignored.

Generation of interrupts from the alarm function is described in Section 9.9.3.

PCF2123_2 © NXP B.V. 2009. All rights reserved.

SPI Real time clock/calendar

<u>Figure 14, Table 22</u> and <u>Table 23</u> show an example for clearing bit AF, but leaving bit MSF and bit TF unaffected. The flags are cleared by a write command, therefore bits 7, 6, 4, 1 and 0 must be written with their previous values. Repeatedly re-writing these bits has no influence on the functional behavior.

To prevent the timer flags being overwritten while clearing bit AF, logic AND is performed during a write access. A flag is cleared by writing logic 0 whilst a flag is not cleared by writing logic 1. Writing logic 1 will result in the flag value remaining unchanged.

Table 22. Flag location in register Control 2

Register	Bit	Bit								
	7	6	5	4	3	2	1	0		
Control_2	-	-	MSF	-	AF	TF	-	-		

<u>Table 23</u> shows what instruction must be sent to clear bit AF. In this example, bit MSF and bit TF are unaffected.

Table 23. Example to clear only AF (bit 3) in register Control_2

Register	Bit	3it								
	7	6	5	4	3	2	1	0		
Control_2	-	-	1	-	0	1	-	-		

9.8 Timer functions

The countdown timer has four selectable source clocks allowing for countdown periods in the range from 244 μs to 4 h 15 min. There are also two pre-defined timers which can be used to generate an interrupt once per second or once per minute. For periods greater than 4 hours, the alarm function can be used. Registers 01h, 0Eh and 0Fh are used to control the timer function and output.

9.8.1 Register Timer_clkout

Table 24. Timer_clkout - timer control register (address 0Eh) bit description

Bit	Symbol	Value	Description	Reference	
7	-	-	unused	-

Table 25. Register Countdown_timer (address 0Ah) bits description

Bit	Symbol	Value	Description	Reference
7 to 0	COUNTDOWN_TIMER[7:0]	0h to FFh	countdown period in seconds:	Section 9.8.4
			$CountdownPeriod = \frac{n}{SourceClockFrequency}$	
			where n is the countdown value	

9.8.3 Minute and second interrupt

The minute and second interrupts (bits MI and SI) are pre-defined timers for generating periodic interrupts. The timers can be enabled independently from one another. However, a minute interrupt enabled on top of a second interrupt will not be distinguishable since it will occur at the same time; see Figure 15.

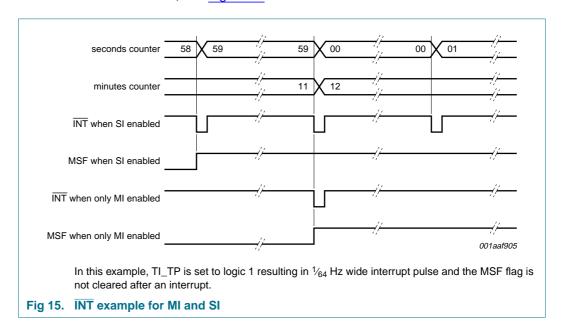

Table 26. Effect of bits MI and SI on INT generation

Minute interrupt (bit MI)	Second interrupt (bit SI)	Result
0	0	no interrupt generated
1	0	an interrupt once per minute
0	1	an interrupt once per second
1	1	an interrupt once per second

The minute and second flag (bit MSF) is set logic 1 when either the seconds or the minutes counter increments according to the currently enabled interrupt. The flag can be read and cleared by the interface. The status of bit MSF does not affect the $\overline{\text{INT}}$ pulse generation. If the MSF flag is not cleared prior to the next coming interrupt period, an $\overline{\text{INT}}$ pulse will still be generated.

The purpose of the flag is to allow the controlling system to interrogate the PCF2123 and identify the source of the interrupt, i.e., minute or second, countdown timer or alarm.

SPI Real time clock/calendar

Table 27. Effect of MI and SI on MSF

Minute interrupt (bit MI)	Second interrupt (bit SI)	Result
0	0	MSF never set
1	0	MSF set when minutes counter increments
0	1	MSF set when seconds counter increments
1	1	MSF set when seconds counter increments

The duration of both of these timers will be affected by the register Offset_register (see Section 9.11). Only when the Offset_register has the value 00h the periods will be consistent.

9.8.4 Countdown timer function

The 8-bit countdown timer at address 0Fh is controlled by the register Timer_clkout at address 0Eh. The register Timer_clkout selects one of 4 source clock frequencies for the timer (4.096 kHz, 64 Hz, 1 Hz, or ${}^{1}/_{60}$ Hz) and enables or disables the timer.

Table 28. Bits CTD0 and CTD1 for timer frequency selection and countdown timer durations

CTD[1:0]	Timer source clock	Delay				
	frequency[1]	Minimum timer duration n = 1	Maximum timer duration n = 255			
00	4.096 kHz	244 μs	62.256 ms			
01	64 Hz	15.625 ms	3.984 s			
10	1 Hz ^[2]	1 s	255 s			
11	½ Hz[2]	60 s	4 h 15 min			

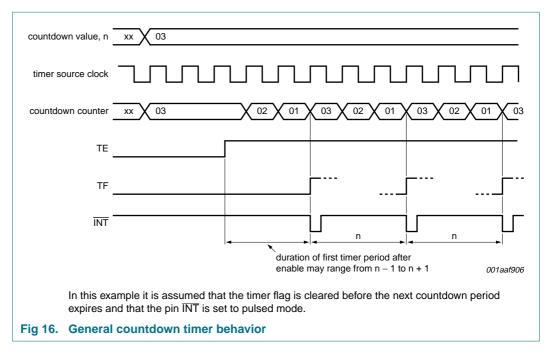

^[1] When not in use, CTD must be set to $\frac{1}{60}$ Hz for power saving.

Remark: Note that all timings which are generated from the 32.768 kHz oscillator are based on the assumption that there is 0 ppm deviation. Deviation in oscillator frequency will result in deviation in timings. This is not applicable to interface timing.

The timer counts down from a software-loaded 8-bit binary value, n. Loading the counter with 0 stops the timer. Values from 1 to 255 are valid. When the counter reaches 1, the countdown timer flag (bit TF) will be set and the counter automatically re-loads and starts the next timer period. Reading the timer will return the current value of the countdown counter (see Figure 16).

^[2] Time periods can be affected by correction pulses.

SPI Real time clock/calendar

If a new value of n is written before the end of the current timer period, then this value will take immediate effect. NXP does not recommend changing n without first disabling the counter (by setting bit TE = 0). The update of n is asynchronous to the timer clock, therefore changing it without setting bit TE = 0 may result in a corrupted value loaded into the countdown counter which results in an undetermined countdown period for the first period. The countdown value n will, however, be correctly stored and correctly loaded on subsequent timer periods.

When the countdown timer flag is set, an interrupt signal on $\overline{\text{INT}}$ will be generated provided that this mode is enabled. See Section 9.9.2 for details on how the interrupt can be controlled.

When starting the timer for the first time, the first period will have an uncertainty which is a result of the enable instruction being generated from the interface clock which is asynchronous from the timer source clock. Subsequent timer periods will have no such delay. The amount of delay for the first timer period will depend on the chosen source clock, see Table 29.

Table 29. First period delay for timer counter value n

Timer source clock	Minimum timer period	Maximum timer period
4.096 kHz	n	n + 1
64 Hz	n	n + 1
1 Hz	$(n-1) + \frac{1}{64} Hz$	n + ¹ / ₆₄ Hz
¹⁄ ₆₀ Hz	$(n-1) + \frac{1}{64} Hz$	n + ½ Hz

At the end of every countdown, the timer sets the countdown timer flag (bit TF). Bit TF may only be cleared by software. The asserted bit TF can be used to generate an interrupt (INT). The interrupt may be generated as a pulsed signal every countdown period or as a permanently active signal which follows the condition of bit TF. Bit TI_TP is used to control this mode selection and the interrupt output may be disabled with bit TIE, see Table 6.

SPI Real time clock/calendar

When reading the timer, the current countdown value is returned and **not** the initial value n. Since it is not possible to freeze the countdown timer counter during read back, it is recommended to read the register twice and check for consistent results.

Timer source clock frequency selection of 1 Hz and $^{1}/_{60}$ Hz will be affected by the Offset_register. The duration of a program period will vary according to when the offset is initiated. For example, if a 100 s timer is set using the 1 Hz clock as source, then some 100 s periods will contain correction pulses and therefor be longer or shorter depending on the setting of the Offset_register. See Section 9.11 to understand the operation of the Offset_register.

9.8.5 Timer flags

When a minute or second interrupt occurs, bit MSF is set logic 1. Similarly, at the end of a timer countdown or alarm event, bit TF or AF are set logic 1. These bits maintain their value until overwritten by software. If both countdown timer and minute or second interrupts are required in the application, the source of the interrupt can be determined by reading these bits. To prevent one flag being overwritten while clearing another a logical AND is performed during a write access. A flag is cleared by writing logic 0 whilst a flag is not cleared by writing logic 1. Writing logic 1 will result in the flag value remaining unchanged.

Three examples are given for clearing the flags. Clearing the flags is made by a write command, therefore bits 7, 6, 4, 1 and 0 must be written with their previous values. Repeatedly re-writing these bits has no influence on the functional behavior.

Table 30. Flag location in register Control_2

Register	Bit								
	7	6	5	4	3	2	1	0	
Control_2	-	-	MSF	-	AF	TF	-	-	

Table 31, Table 32 and Table 33 show what instruction must be sent to clear the appropriate flag.

Table 31. Example to clear only TF (bit 2) in register Control_2

Register	Bit								
	7	6	5	4	3	2	1	0	
Control_2	-	-	1	-	1	0	-	-	

Table 32. Example to clear only MSF (bit 5) in register Control_2

Register	Bit								
	7	6	5	4	3	2	1	0	
Control_2	-	-	0	-	1	1	-	-	

Table 33. Example to clear both TF and MSF (bit 2 and bit 5) in register Control_2

Register	Bit							
	7	6	5	4	3	2	1	0
Control_2	-	-	0	-	1	0	-	-

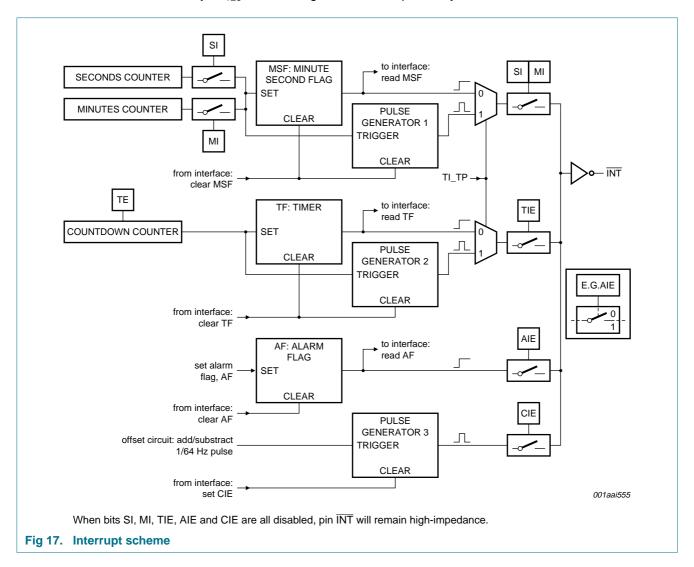

Clearing the alarm flag (bit AF) operates in exactly the same way, see Section 9.7.5.

SPI Real time clock/calendar

9.9 Interrupt output

An active LOW interrupt signal is available at pin $\overline{\text{INT}}$. Operation is controlled via the bits of register Control_2. Interrupts may be sourced from four places: second and minute timer, countdown timer, alarm function or offset function.

With bit TI_TP, the timer generated interrupts can be configured to either generate a pulse or to follow the status of the interrupt flags (bits TF and MSF). Correction interrupt pulses are always $\frac{1}{128}$ second long. Alarm interrupts always follow the condition of AF.

Remark: Note that the interrupts from the four sources are wired-OR, meaning they will mask one another (see Figure 17).

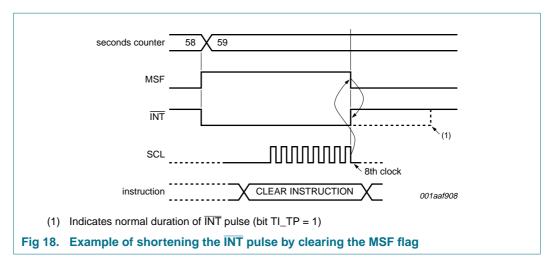

9.9.1 Minute and second interrupts

The pulse generator for the minute and second interrupt operates from an internal 64 Hz clock and consequently generates a pulse of $\frac{1}{64}$ second in duration.

PCF2123_2 © NXP B.V. 2009. All rights reserved.

SPI Real time clock/calendar

If the MSF flag is cleared before the end of the $\overline{\text{INT}}$ pulse, then the $\overline{\text{INT}}$ pulse is shortened. This allows the source of a system interrupt to be cleared immediately it is serviced, i.e., the system does not have to wait for the completion of the pulse before continuing; see Figure 18. Instructions for clearing MSF are given in Section 9.8.5.

The timing shown for clearing bit MSF in <u>Figure 18</u> is also valid for the non-pulsed interrupt mode i.e. when bit $TI_TP = 0$, \overline{INT} may be shortened by setting both MI and SI or MSF to logic 0.

9.9.2 Countdown timer interrupts

The generation of interrupts from the countdown timer is controlled via bit TIE.

The pulse generator for the countdown timer interrupt also uses an internal clock, but this time it is dependent on the selected source clock for the countdown timer and on the countdown value n. As a consequence, the width of the interrupt pulse varies (see Table 34).

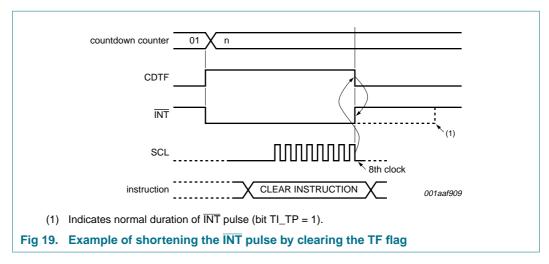

Table 34. INT operation (bit TI_TP = 1)

Source clock (Hz)	INT period (s)			
	n = 1[1]	n > 1		
4096	1/8192	1/4096		
64	¹ / ₁₂₈	1/64		
1	1/64	1/64		
1/60	1/64	1/64		

^[1] n = loaded countdown value. Timer stopped when n = 0.

If the TF flag is cleared before the end of the $\overline{\text{INT}}$ pulse, then the $\overline{\text{INT}}$ pulse is shortened. This allows the source of a system interrupt to be cleared immediately it is serviced, i.e., the system does not have to wait for the completion of the pulse before continuing (see Figure 19). Instructions for clearing MSF can be found in Section 9.8.5.

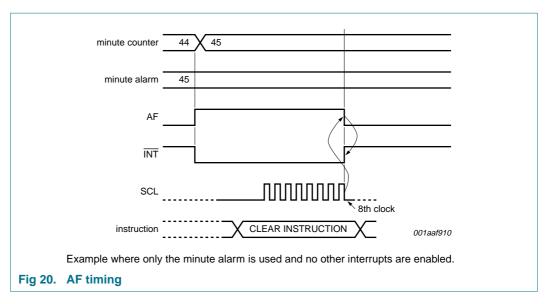

SPI Real time clock/calendar

The timing shown for clearing bit TF in Figure 19 is also valid for the non-pulsed interrupt mode, i.e., when bit $TI_TP = 0$; \overline{INT} may be shortened by setting bit TIE to logic 0.

9.9.3 Alarm interrupts

The generation of interrupts from the alarm function is controlled via bit AIE (see <u>Table 6</u>). If bit AIE is enabled, the <u>INT</u> pin follows the condition of bit AF. Clearing bit AF will immediately clear <u>INT</u>. No pulse generation is possible for alarm interrupts (see <u>Figure 20</u>).

9.9.3.1 Correction pulse interrupts

Interrupt pulses generated by correction events can be shortened by writing logic 1 to bit CIE in register Control_1.

SPI Real time clock/calendar

9.10 Clock output

A programmable square wave is available at pin CLKOUT. Operation is controlled by the COF[2:0] bits in the register Timer_clkout. Frequencies of 32.768 kHz (default) down to 1 Hz can be generated for use as a system clock, microcontroller clock, input to a charge pump, or for calibration of the oscillator.

Pin CLKOUT is an open-drain output and enabled at power-on. When disabled the output is high-impedance.

The duty cycle of the selected clock is not controlled. However, due to the nature of the clock generation, all will be 50 : 50 except the 32.768 kHz frequencies.

The STOP bit function can also affect the CLKOUT signal, depending on the selected frequency. When the STOP bit is set to logic 1, the CLKOUT pin will generate a continuous LOW for those frequencies that can be stopped. For more details of the STOP bit function see Section 9.13.

Table 35. CLKOUT frequency selection

Bits COF[2:0]	CLKOUT frequency (Hz)	Typical duty cycle[1]	Effect of STOP bit
000	32768	60:40 to 40:60	no effect
001	16384	50 : 50	no effect
010	8192	50 : 50	no effect
011	4096	50 : 50	CLKOUT = LOW
100	2048	50 : 50	CLKOUT = LOW
101	1024	50 : 50	CLKOUT = LOW
110	1[2]	50:50	CLKOUT = LOW
111	CLKOUT = high-Z	-	-

^[1] Duty cycle definition: % HIGH-level time : % LOW-level time.

9.10.1 CLKOE pin

The CLKOE pin can be used to block the CLKOUT function and force the CLKOUT pin to an high-impedance state. The effect is the same as setting COF[2:0] = 111.

9.11 Offset register

The PCF2123 incorporates an offset register (address 0Dh) which can be used to implement several functions, such as:

- · Ageing adjustment
- Temperature compensation
- Accuracy tuning

The offset is made once every two hours in the normal mode, or once every hour in the course mode. Each LSB will introduce an offset of 2.17 ppm for normal mode and 4.34 ppm for course mode. The values of 2.17 ppm and 4.34 ppm are based on a nominal 32.768 kHz clock. The offset value is coded in two's complement giving a range of +63 LSB to -64 LSB.

^{[2] 1} Hz clock pulses will be affected by offset correction pulses.

SPI Real time clock/calendar

Table 36. Register Offset_register

OFFSET[6:0]	Offset value in	Offset value in ppm		
	decimal	Normal mode MODE = 0	Course mode MODE = 1	
0 1 1 1 1 1 1	+63	+136.71	+273.42	
0 1 1 1 1 1 0	+62	+134.54	+269.08	
:	:	:	:	
0 0 0 0 0 1 0	+2	+4.34	+8.68	
0 0 0 0 0 0 1	+1	+2.17	+4.34	
0 0 0 0 0 0 0	0[1]	0	0	
1 1 1 1 1 1 1	-1	-2.17	-4.34	
1 1 1 1 1 1 0	-2	-4.34	-8.68	
:	:	:	:	
1 0 0 0 0 0 1	-63	-136.71	-273.42	
1 0 0 0 0 0 0	-64	-138.88	-277.76	

^[1] Default mode.

The correction is made by adding or subtracting 64 Hz clock correction pulses, thereby changing the period of a single second.

Table 37. Example of converting the offset in ppm to seconds

Offset in ppm	Seconds per			
	Day	Week	Month	Year
2.17	0.187	1.31	5.69	68.2
4.34	0.375	2.62	11.4	136

In normal mode, the correction is triggered once per two hours and then correction pulses are applied once per minute until the programmed correction values has been implement.

In course mode, the correction is triggered once per hour and then correction pulses are applied once per minute up to a maximum of 60 minutes. When correction values greater than 60 are used, additional correction pulses are made in the 59th minute (see <u>Table 38</u>).

SPI Real time clock/calendar

Table 38. Correction pulses for course mode

Correction value	Hour:Minute ^[1]	Correction pulses on INT per minute[2]
+1 or –1	02:00	1
	02:01 to 02:59	0
+2 or –2	02:00	1
	02:01	1
	02:02 to 02:59	0
+3 or –3	02:00	1
	02:01	1
	02:02	1
	02:03 to 02:59	0
:	:	:
+59 or –59	02:00 to 02:58	1
	02:59	0
+60 or –60	02:00 to 02:59	1
+61 or –61	02:00 to 02:58	1
	02:59	2
+62 or –62	02:00 to 02:58	1
	02:59	3
+63 or –63	02:00 to 02:58	1
	02:59	4
-64	02:00 to 02:58	1
	02:59	5

^[1] Example is given in a time range from 2:00 to 2:59.

It is possible to monitor when correction pulses are applied. The correction interrupt enable mode (bit CIE) will generate a $^{1}\!\!/_{128}$ second pulse on $\overline{\rm INT}$ for every correction applied. In the case where multiple correction pulses are applied, a $^{1}\!\!/_{128}$ second interrupt pulse will be generated and repeated every $^{1}\!\!/_{64}$ seconds.

Correction is applied to the 1 Hz clock. Any timer or clock output using a frequency of 1 Hz or below will also be affected by the correction pulses.

^[2] Correction $\overline{\text{INT}}$ pulses are $^{1/}_{128}$ s wide. For multiple pulses they are repeated at $^{1/}_{64}$ s interval.

SPI Real time clock/calendar

Table 39. Effect of correction pulses

Frequency (Hz)	Effect of correction
CLKOUT	
32768	no effect
16384	no effect
8192	no effect
4096	no effect
2048	no effect
1024	no effect
1	effected
Time source clock	
4096	no effect
64	no effect
1	effected
1/60	effected

9.12 External clock test mode

A test mode is available which allows for on-board testing. In this mode it is possible to set up test conditions and control the operation of the RTC.

The test mode is entered by setting bit EXT_TEST in register Control_1. Then pin CLKOUT becomes an input. The test mode replaces the internal clock signal with the signal applied to pin CLKOUT.

The signal applied to pin CLKOUT should have a minimum pulse width of 300 ns and a maximum period of 1000 ns. The internal clock, now sourced from CLKOUT, is divided down to 1 Hz by a 2⁶ divide chain called a prescaler. The prescaler can be set into a known state by using bit STOP. When bit STOP is set, the prescaler is reset to 0. (STOP must be cleared before the prescaler can operate again.)

From a stop condition, the first 1 second increment will take place after 32 positive edges on pin CLKOUT. Thereafter, every 64 positive edges will cause a 1 second increment.

Remark: Entry into test mode is not synchronized to the internal 64 Hz clock. When entering the test mode, no assumption as to the state of the prescaler can be made.

Operation example:

- 1. Set EXT_TEST test mode (register Control_1, bit EXT_TEST = 1).
- 2. Set STOP (Control_1, bit STOP = 1).
- 3. Clear STOP (Control 1, bit STOP = 0).
- 4. Set time registers to desired value.
- 5. Apply 32 clock pulses to pin CLKOUT.
- 6. Read time registers to see the first change.

SPI Real time clock/calendar

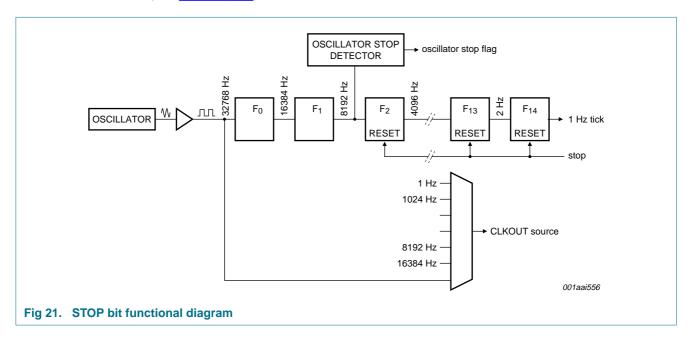

- 7. Apply 64 clock pulses to pin CLKOUT.
- 8. Read time registers to see the second change.

Repeat 7 and 8 for additional increments.

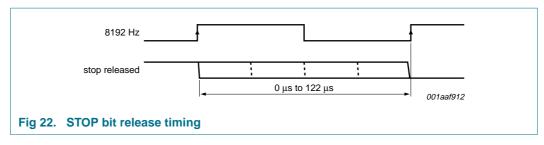

9.13 STOP bit function

The function of the STOP bit is to allow for accurate starting of the time circuits. The STOP bit function will cause the upper part of the prescaler (F_2 to F_{14}) to be held in reset and thus no 1 Hz ticks will be generated. The time circuits can then be set and will not increment until the STOP bit is released (see Figure 22 and Table 40).

The STOP bit function will not affect the output of 32.768 kHz, 16.384 kHz or 8.192 kHz (see Section 9.10).

The lower two stages of the prescaler (F_0 and F_1) are not reset and because the SPI-bus is asynchronous to the crystal oscillator, the accuracy of re-starting the time circuits will be between 0 and one 8.192 kHz cycle (see Figure 22).

The first increment of the time circuits is between 0.499888 s and 0.500000 s after STOP bit is released. The uncertainty is caused by the prescaler bits F_0 and F_1 not being reset (see Table 40).

SPI Real time clock/calendar

Table 40. First increment of time circuits after STOP bit release

Bit	Prescaler bits	1 Hz tick	Time	Comment
STOP	F ₀ F ₁ -F ₂ to F ₁₄		hh:mm:ss	
Clock is	running normally			
0	01-0 0001 1101 0100		12:45:12	prescaler counting normally

	00-0 0000 0000 0001	·	08:00:02	0 to 1 transition of F ₁₄ increments the time circuits

^[1] F_0 is clocked at 32.768 kHz.

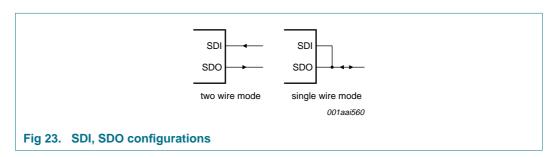

9.14 3-line serial interface

Data transfer to and from the device is made via a 3-wire SPI-bus (see <u>Table 41</u>). The data lines for input and output are split. The data input and output lines can be connected together to facilitate a bidirectional data bus. The chip enable signal is used to identify the transmitted data. Each data transfer is a byte, with the Most Significant Bit (MSB) sent first (see <u>Figure 24</u>).

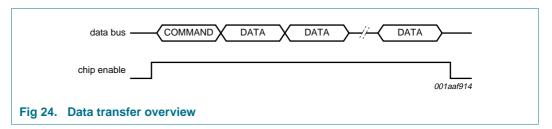

SPI Real time clock/calendar

Table 41. Serial interface

Symbol	Function	Description
CE	chip enable input	when LOW, the interface is reset; pull-down resistor included; active input may be higher than $V_{\text{DD}},$ but may not be wired permanently HIGH
SCL	serial clock input	when CE is LOW, this input may float; input may be higher than $\ensuremath{V_{DD}}$
SDI	serial data input	when CE is LOW, input may float; input may be higher than V_{DD} ; input data is sampled on the rising edge of SCL
SDO	serial data output	push-pull output; drives from V_{SS} to V_{DD} ; output data is changed on the falling edge of SCL; will be high-Z when not driving; may be connected directly to SDI

The transmission is controlled by the active HIGH chip enable signal CE. The first byte transmitted is the command byte. Subsequent bytes will be either data to be written or data to be read. Data is sampled on the rising edge of the clock and transferred internally on the falling edge.

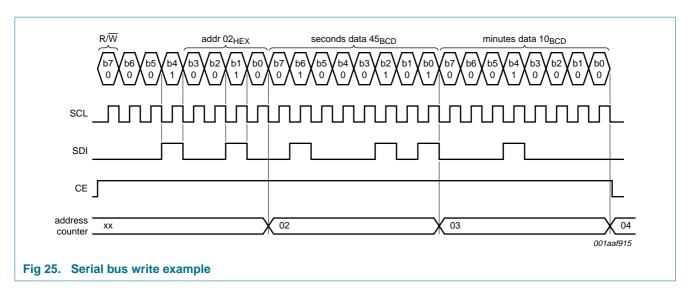

The command byte defines the address of the first register to be accessed and the read/write mode. The address counter will auto increment after every access and will rollover to zero after the last register is accessed. The read/write bit (R/\overline{W}) defines if the following bytes will be read or write information.

Table 42. Command byte definition

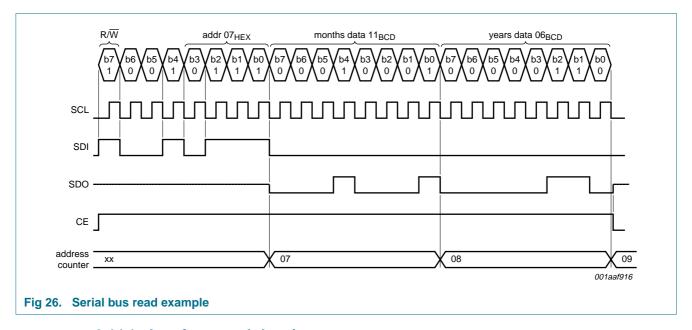

Bit	Symbol	Value	Description
7	R/\overline{W}		data read or data write selection
		0	write data
		1	read data
6 to 4	SA	001	subaddress; other codes will cause the device to ignore data transfer
3 to 0	RA	0h to Fh	register address range

In <u>Figure 25</u>, the register Seconds is set to 45 seconds and the register Minutes is set to 10 minutes.

SPI Real time clock/calendar

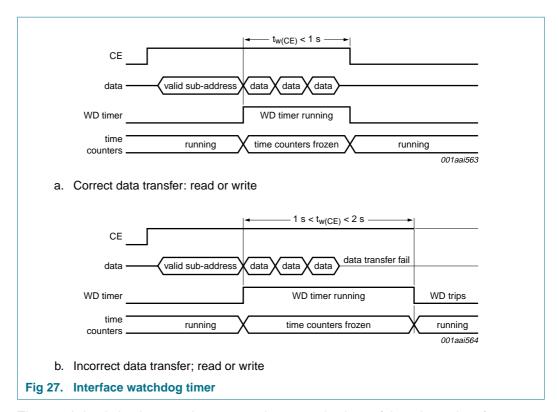

In <u>Figure 26</u>, the Months and Years registers are read. In this example, pins SDI and SDO are not connected together. For this configuration, it is important that pin SDI is never left floating. It must always be driven either HIGH or LOW. If pin SDI is left open, high I_{DD} currents may result. Short transition periods in the order of 200 ns will not cause any problems.

9.14.1 Interface watchdog timer

During read/write operations, the time counting circuits are frozen. To prevent a situation where the accessing device becomes locked and does not clear the interface by setting pin CE LOW, the PCF2123 has a built in watchdog timer. Should the interface be active for more than 1 s from the time a valid subaddress is transmitted, then the PCF2123 will automatically clear the interface and allow the time counting circuits to continue counting. CE must return LOW once more before a new data transfer can be executed.

SPI Real time clock/calendar

The watchdog is implemented to prevent the excessive loss of time due to interface access failure e.g. if main power is removed from a battery backed-up system during an interface access.

Each time the watchdog period is exceeded, 1 s will be lost from the time counters. The watchdog will trigger between 1 s and 2 s after receiving a valid subaddress.

SPI Real time clock/calendar

10. Limiting values

Table 43. Limiting values

In accordance with the Absolute Maximum Rating System (IEC 60134).

		• • •	,		
Symbol	Parameter	Conditions	Min	Max	Unit

- [1] The x/y coordinates of the alignment mark location represent the position of the REF point (see <u>Figure 34</u>) with respect to the center (x/y = 0) of the chip; see <u>Figure 32</u> and <u>Figure 33</u>.
- [2] The x/y values of the dimensions represent the extensions of the alignment mark in direction of the coordinate axis (see Figure 34).

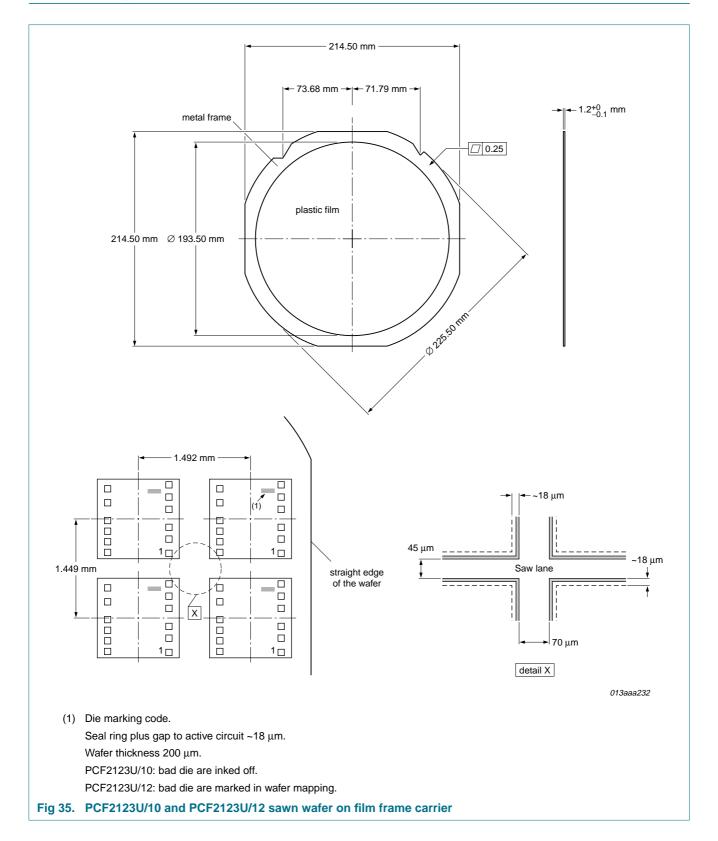

SPI Real time clock/calendar

16. Handling information

All input and output pins are protected against ElectroStatic Discharge (ESD) under normal handling. When handling Metal-Oxide Semiconductor (MOS) devices ensure that all normal precautions are taken as described in *JESD625-A*, *IEC 61340-5* or equivalent standards.

17. Packing information

SPI Real time clock/calendar

18. Soldering of SMD packages

This text provides a very brief insight into a complex technology. A more in-depth account of soldering ICs can be found in Application Note *AN10365 "Surface mount reflow soldering description"*.

18.1 Introduction to soldering

Soldering is one of the most common methods through which packages are attached to Printed Circuit Boards (PCBs), to form electrical circuits. The soldered joint provides both the mechanical and the electrical connection. There is no single soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and Surface Mount Devices (SMDs) are mixed on one printed wiring board; however, it is not suitable for fine pitch SMDs. Reflow soldering is ideal for the small pitches and high densities that come with increased miniaturization.

18.2 Wave and reflow soldering

Wave soldering is a joining technology in which the joints are made by solder coming from a standing wave of liquid solder. The wave soldering process is suitable for the following:

- Through-hole components
- Leaded or leadless SMDs, which are glued to the surface of the printed circuit board

Not all SMDs can be wave soldered. Packages with solder balls, and some leadless packages which have solder lands underneath the body, cannot be wave soldered. Also, leaded SMDs with leads having a pitch smaller than ~0.6 mm cannot be wave soldered, due to an increased probability of bridging.

The reflow soldering process involves applying solder paste to a board, followed by component placement and exposure to a temperature profile. Leaded packages, packages with solder balls, and leadless packages are all reflow solderable.

Key characteristics in both wave and reflow soldering are:

- Board specifications, including the board finish, solder masks and vias
- · Package footprints, including solder thieves and orientation
- The moisture sensitivity level of the packages
- Package placement
- Inspection and repair
- Lead-free soldering versus SnPb soldering

18.3 Wave soldering

Key characteristics in wave soldering are:

- Process issues, such as application of adhesive and flux, clinching of leads, board transport, the solder wave parameters, and the time during which components are exposed to the wave
- Solder bath specifications, including temperature and impurities

SPI Real time clock/calendar

18.4 Reflow soldering

Key characteristics in reflow soldering are:

- Lead-free versus SnPb soldering; note that a lead-free reflow process usually leads to higher minimum peak temperatures (see <u>Figure 36</u>) than a SnPb process, thus reducing the process window
- Solder paste printing issues including smearing, release, and adjusting the process window for a mix of large and small components on one board
- Reflow temperature profile; this profile includes preheat, reflow (in which the board is heated to the peak temperature) and cooling down. It is imperative that the peak temperature is high enough for the solder to make reliable solder joints (a solder paste characteristic). In addition, the peak temperature must be low enough that the packages and/or boards are not damaged. The peak temperature of the package depends on package thickness and volume and is classified in accordance with Table 49 and 50

Table 49. SnPb eutectic process (from J-STD-020C)

Package thickness (mm)	Package reflow temperature (°C) Volume (mm³)				
	< 350	≥ 350			
< 2.5	235	220			
≥ 2.5	220	220			

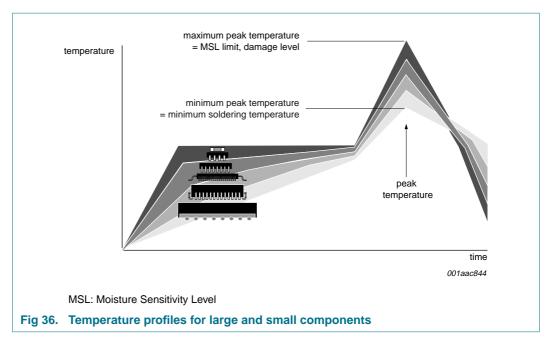

Table 50. Lead-free process (from J-STD-020C)

Package thickness (mm)	ckage thickness (mm) Package reflow temperature (°C)					
	Volume (mm ³)	(mm ³)				
	< 350	350 to 2000	> 2000			
< 1.6	260	260	260			
1.6 to 2.5	260	250	245			
> 2.5	250	245	245			

Moisture sensitivity precautions, as indicated on the packing, must be respected at all times.

Studies have shown that small packages reach higher temperatures during reflow soldering, see Figure 36.

SPI Real time clock/calendar

For further information on temperature profiles, refer to Application Note *AN10365* "Surface mount reflow soldering description".

22.1 Data sheet status

Document status[1][2]	Product status[3]	Definition
Objective [short] data sheet	Development	This document contains data from the objective specification for product development.
Preliminary [short] data sheet	Qualification	This document contains data from the preliminary specification.
Product [short] data sheet	Production	This document contains the product specification.

- [1] Please consult the most recently issued document before initiating or completing a design.
- [2] The term 'short data sheet' is explained in section "Definitions"
- [3] The product status of device(s) described in this document may have changed since this document was published and may differ in case of multiple devices. The latest product status information is available on the Internet at URL http://www.nxp.com.

22.2 Definitions

Draft — The document is a draft version only. The content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included herein and shall have no liability for the consequences of use of such information.

Short data sheet — A short data sheet is an extract from a full data sheet with the same product type number(s) and title. A short data sheet is intended for quick reference only and should not be relied upon to contain detailed and full information. For detailed and full information see the relevant full data sheet, which is available on request via the local NXP Semiconductors sales office. In case of any inconsistency or conflict with the short data sheet, the full data sheet shall prevail.

22.3 Disclaimers

General — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors accepts no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Limiting values — Stress above one or more limiting values (as defined in the Absolute Maximum Ratings System of IEC 60134) may cause permanent damage to the device. Limiting values are stress ratings only and operation of the device at these or any other conditions above those given in the Characteristics sections of this document is not implied. Exposure to limiting values for extended periods may affect device reliability.

Terms and conditions of sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, including those pertaining to warranty, intellectual property rights infringement and limitation of liability, unless explicitly otherwise agreed to in writing by NXP Semiconductors. In case of any inconsistency or conflict between information in this document and such terms and conditions, the latter will prevail.

No offer to sell or license — Nothing in this document may be interpreted or construed as an offer to sell products that is open for acceptance or the grant, conveyance or implication of any license under any copyrights, patents or other industrial or intellectual property rights.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from national authorities.

Bare die — All die are tested on compliance with their related technical specifications as stated in this data sheet up to the point of wafer sawing and are handled in accordance with the NXP Semiconductors storage and transportation conditions. If there are data sheet limits not guaranteed, these will be separately indicated in the data sheet. There are no post-packing tests performed on individual die or wafers.

NXP Semiconductors has no control of third party procedures in the sawing, handling, packing or assembly of the die. Accordingly, NXP Semiconductors assumes no liability for device functionality or performance of the die or systems after third party sawing, handling, packing or assembly of the die. It is the responsibility of the customer to test and qualify their application in which the die is used.

All die sales are conditioned upon and subject to the customer entering into a written die sale agreement with NXP Semiconductors through its legal department.
